### 1. Overview

Our goal is to understand the proof of the following theorem:

**THEOREM 0.1.**  $\dim_{\mathbb{Q}} H^{4g-6}(\mathcal{M}_g, \mathbb{Q})$  grows exponentially with  $g$ .

**REMARK 0.1.**  $\mathcal{M}_g$  has complex dimension  $3g - 3$ .

This theorem defied previous expectations.

**CONJECTURE 1** (Kontsevich (1993), Church-Farb-Putman (2014)). For fixed  $k > 0$ ,  $H^{4g-4-k}(\mathcal{M}_g, \mathbb{Q}) = 0$  for  $g \gg 0$ .

The structure of the course is as follows.

- Constructing the moduli space
  - (1) Nodal curves and stable reduction theorem
  - (2) Deformation theory of nodal curves
  - (3) The Deligne-Mumford moduli space of stable curves (1969)
- Cohomology
  - (1) Mixed Hodge structure on the cohomology of a smooth variety (early 1970s)
  - (2) Dual complexes of normal crossings divisors (tropical geometry)
  - (3) Boundary complex of  $\mathcal{M}_g$  (tropical moduli space)
- Cohomology of  $\mathcal{M}_h$ 
  - (1) Stable cohomology (Madsen-Weiss 2007)
  - (2) Virtual cohomological dimension of  $\mathcal{M}_g$  (Harer 84) (Vanishing of  $H^{4g-5}$  (Church-Farb-Putman, Morita-Sakasai-Suzuki))
  - (3) Euler characteristic of  $\mathcal{M}_g$  (Harer-Zagier 86)
- Graph complexes (Kontsevich 93)
  - (1) Feynman amplitudes and wheel classes. See Fig. 1 for the 5-wheel.
  - (2) Grothendieck-Teichmüller Lie algebra
  - (3) Willwacher's theorem
- Mixed Tate motives (MTM) over  $\mathbb{Z}$ 
  - (1) Mixed Tate motives
  - (2) Brown's theorem (conjecture of Deligne-Ihara): "Soulé elements (closely related to Drinfeld's associators) generate a free Lie subalgebra."
  - (3) Proof of exponential growth of  $H^{4g-6}$ .

## Part 1

# Constructing the moduli space

## CHAPTER 1

# Nodal curves and stable reduction theorem

### 1. Nodal curves

We will work over  $\mathbb{C}$ . We want to show that nodal curves, and families thereof, can be written in a normal form in local coordinates. We will follow chapter X of [1].

**DEFINITION 1.1.** A *nodal curve* is a complete curve such that every singular point has a neighborhood isomorphic (analytically over  $\mathbb{C}$ ) to a neighborhood of 0 in  $(xy = 0) \subset \mathbb{C}^2$ .

**DEFINITION 1.2.** A *family of nodal curves* over a base  $S$  is a flat proper surjective morphism  $\mathcal{C} \rightarrow S$  such that every geometric fiber is a nodal curve.

Recall that a flat morphism is the agreed upon notion of a map for which the fibers form a continuously varying family of schemes (or complex analytic spaces, varieties, etc.). Properness is saying that nothing can “disappear” as we approach any particular point in the base.

**Proposition 1.1.** *Let  $\pi : X \rightarrow S$  be a proper surjective morphism of  $\mathbb{C}$ -analytic spaces. This is a family of nodal curves iff at every point  $p \in X$  either  $\pi$  is smooth at  $p$  with one-dimensional fiber, or there is a neighborhood of  $p$  which is isomorphic (over  $S$ ) to a neighborhood of  $(0, s)$  in  $(xy = F) \subseteq \mathbb{C}^2 \times S$  where  $s = \pi(p)$  and  $F \in \mathfrak{m}_S \subseteq \mathcal{O}_{S,s}$ .*

**Lemma 1.2.** *Let  $f$  be holomorphic at  $0 \in \mathbb{C}^2$ . Then  $(f = 0)$  has a node at 0 iff*

$$(1.1) \quad 0 = f = \frac{\partial f}{\partial x} = \frac{\partial f}{\partial y}$$

*at 0, and the Hessian of  $f$  at 0 is non-singular.*

This tells us that these nodes are the “simplest” possible singularities.

**PROOF.** ( $\implies$ ): This direction is immediate.

( $\impliedby$ ): Suppose  $0 = f = \partial_x f = \partial_y f$  at 0. Then

$$(1.2) \quad f = a - x^2 + 2bxy + cy^2$$

where  $a$ ,  $b$ , and  $c$  are holomorphic functions. The Hessian is

$$(1.3) \quad \begin{pmatrix} 2a & 2b \\ 2b & 2c \end{pmatrix}$$

so being non-singular means exactly that

$$(1.4) \quad b^2 - ac \neq 0.$$

After possibly making a linear change of coordinates, we can assume  $a \neq 0$ , and change to coordinates

$$(1.5) \quad x_1 = x + \frac{b}{a}y \qquad y_1 = y$$

so we can write

$$(1.6) \quad f = a_1 x_1^2 + c_1 y_1^2$$

where  $a_1(0), c_1(0) \neq 0$ . Choose square roots<sup>1.1</sup>  $\alpha$  and  $\gamma$  of  $a_1$  and  $c_1$ . Now replace  $x_1$  and  $y_1$  by  $x_2 = \alpha x_1$  and  $y_2 = \gamma y_1$  so that

$$(1.7) \quad f = x_2^2 + y_2^2.$$

Now for  $x_3 = x_2 + iy_2$  and  $y_3 = x_2 - iy_2$ , we have  $f = x_3 y_3$ .  $\square$

PROOF OF PROPOSITION 1.1. Let  $\pi : X \rightarrow S$  be proper and surjective. Consider  $x \in X$ . Then either  $\pi$  is smooth with 1-dimensional fiber at  $x$  (nothing to show) or  $x$  is a node in  $\pi^{-1}(s)$ ,  $s = \pi(x)$ . Locally near  $x$  we can embed  $X \subseteq \mathbb{C}^r \times S$ . This is locally closed (over  $S$ ). Now we have a left exact sequence of tangent spaces:

$$(1.8) \quad 0 \rightarrow T_x X_s \rightarrow T_x X \rightarrow T_s S$$

where  $\dim T_x X_s = 2$ . Now choose a linear projection  $\mathbb{C}^r \rightarrow \mathbb{C}^2$  which is an isomorphism on  $T_x X_s$ . Using this projection we get a composition:

$$(1.9) \quad T_x X \subseteq \mathbb{C}^r \times T_s S \rightarrow \mathbb{C}^2 \times T_s S$$

and we claim this is injective. Then the implicit function theorem tells us that there is a neighborhood of  $x$  which embeds in  $\mathbb{C}^2 \times S$  (over  $S$ ). We should think of this as a family of plane curves: each fiber has a single defining equation. More specifically we have the following.

FACT 1 ([Lemma 31.18.9 \(Stacks project\)](#)). *If  $\mathcal{Y} \rightarrow S$  is a smooth morphism and  $D \subseteq \mathcal{Y}$  is flat over  $S$ , codimension 1 in  $\mathcal{Y}$ , then  $D$  is a Cartier divisor.*

By Fact 1,  $X \subseteq \mathbb{C}^2 \times S$  is locally defined by a single equation  $F = 0$ . Now consider  $\partial_x F$ ,  $\partial_y F$ , and the Hessian of  $F$  with respect to  $x$  and  $y$ . Then the proof of Lemma 1.2 shows that

$$(1.10) \quad F = x_3 y_3 - f$$

where  $f$  is a function on  $S$  which vanishes at  $s$ .  $\square$

Lecture 3; January  
27, 2020

## 2. Stability of nodal curves

The following is a corollary of Proposition 1.1.

**Corollary 1.3.** *A family of nodal curves  $\pi : X \rightarrow S$  is a local complete intersection (lci) morphism.*

This implies that there is a relative dualizing sheaf  $\omega_{X/S}$  which is locally free of rank 1.

---

<sup>1.1</sup>There is some subtlety here since these are functions rather than scalars. Because  $a_1$  and  $c_1$  are nonzero at 0, we can ensure that the image of  $a_1$  and  $c_1$  are, say, contained in an open half space. Now we can choose a branch of log which is defined on this half space. Then multiply by 1/2 and exponentiate.

FIGURE 1. The normalization of a nodal curve. The nodal points of  $C$  each have two preimages under the normalization  $\nu$ .

**2.1. Serre duality.** The point here is that the duality properties that we already know about for smooth curves extend naturally to nodal ones.

Let  $C$  be a nodal curve (over a point). There is a (natural) isomorphism  $H^1(C, \omega_C) \cong \mathbb{C}$ . Then Serre duality tells us that for any coherent sheaf  $\mathcal{F}$  on  $C$ ,

$$(1.11) \quad H^1(C, \mathcal{F}) \times \text{Hom}(\mathcal{F}, \omega_C) \rightarrow H^1(C, \omega_C) \cong \mathbb{C}$$

is a perfect pairing, i.e.

$$(1.12) \quad H^1(C, \mathcal{F}) \cong \text{Hom}(\mathcal{F}, \omega_C)^\vee.$$

In particular, if  $\mathcal{F}$  is a vector bundle, then

$$(1.13) \quad H^1(C, \mathcal{F}) \cong H^0(C, \mathcal{F}^\vee \otimes \omega_C)^\vee.$$

We can form the normalization<sup>1,2</sup> of a nodal curve as in Fig. 1.

Suppose  $C$  is nodal with components  $C_1, \dots, C_s$  and nodes  $x_1, \dots, x_r$ . Let  $\tilde{C} \xrightarrow{\nu} C$  be the normalization. Write  $\tilde{C}_i$  for the normalization of  $C_i$  and

$$(1.14) \quad \{p_j, q_j\} = \nu^{-1}(x_j)$$

(for  $i \in \{1, \dots, s\}$  and  $j \in \{1, \dots, r\}$ ).

A line bundle  $L$  on  $C$  has *multi-degree*  $\underline{\deg}(L)$  to be

$$(1.15) \quad \underline{\deg}(L) = (\deg(L|_{C_1}), \dots, \deg(L|_{C_s}))$$

$$(1.16) \quad = \left( \deg(\nu^*L|_{\tilde{C}_1}), \dots, \deg(\nu^*L|_{\tilde{C}_s}) \right).$$

The following is a corollary to Serre duality.

**Corollary 1.4.** *If  $C$  is connected, and  $\underline{\deg}(L) > \underline{\deg}(\omega_C)$  then  $H^1(C, L) = 0$ .*

By  $\underline{\deg}(L) > \underline{\deg}(\omega_C)$  we mean that  $\deg(L|_{C_i}) \geq \deg(\omega_C|_{C_i})$  for all  $i$  and  $\underline{\deg}(L) \neq \underline{\deg}(\omega_C)$ .

<sup>1,2</sup>Locally, the corresponding algebraic construction is taking the integral closure of the coordinate ring.

PROOF. First note

$$(1.17) \quad H^1(C, L) \cong H^0(C, \omega_C \otimes L^{-1}) .$$

and  $\deg(\omega_C \otimes L^{-1}) < 0$ .

On any connected component  $C_i$  such that  $\deg(\omega_C \otimes L^{-1})|_{C_i} < 0$  all sections vanish. And all sections vanish on components that meet  $C_i$ , etc.  $\square$

**Corollary 1.5.**  *$L$  is ample if and only if  $\deg(L|_{C_i}) > 0$  for all  $i$ .*

PROOF. ( $\implies$ ): This direction is clear. The restriction of ample  $L$  to any component is still ample.

( $\impliedby$ ): Suppose  $\deg(L|_{C_i}) > 0$ . It is enough to show that  $L^{\otimes N}$  is very ample for some  $N$ . Choose  $N$  sufficiently large so that

$$(1.18) \quad \deg(L^{\otimes N}|_{C_i}) > \deg(\omega_C|_{C_i}) + 2 .$$

Let  $S \subseteq C$  be the union of two distinct smooth points. Then we have a short exact sequence

$$(1.19) \quad 0 \rightarrow I_S \rightarrow \mathcal{O}_C \rightarrow \mathcal{O}_S \rightarrow 0$$

which we can tensor with  $L^{\otimes N}$  to get a sequence which is still exact, which gives us a long exact sequence

$$(1.20) \quad 0 \rightarrow H^0(L^{\otimes N}(-s)) \rightarrow H^0(L^{\otimes N}) \rightarrow H^0(L^{\otimes N}|_S) \rightarrow H^1(L^{\otimes N}(-s)) \rightarrow \dots$$

but  $H^1(L(-s)) = 0$ , so we have a surjection

$$(1.21) \quad H^0(L) \twoheadrightarrow H^0(L|_S) .$$

This shows that sections of  $L^{\otimes N}$  separate the two points in  $S$ . Similar arguments show that sections of high tensor powers of  $L$  separate arbitrary pairs of points and tangent vectors. Therefore, high tensor powers of  $L$  are very ample, and so  $L$  is ample.  $\square$

### 3. Description of $\omega_C$

We now describe the canonical sheaf of a nodal curve in terms of meromorphic differential forms. See [5, Chapter 6] or [2, Chapter 3, Section A] for proofs and further details.

**Proposition 1.6.** *Let  $C$  be a nodal curve with nodes  $x_1, \dots, x_r$ , write  $(p_i, q_i) = \nu^{-1}(x_i)$ . Then*

$$(1.22) \quad \omega_C \cong \nu_* \left( \omega'_{\tilde{C}}(p_1 + q_1 + \dots + p_r + q_r) \right)$$

where  $\omega'_{\tilde{C}}(p_1 + \dots + q_r) \subseteq \omega_{\tilde{C}}(p_1, \dots, q_r)$  is the subsheaf where

$$(1.23) \quad \text{res}_{p_i}(\omega) + \text{res}_{q_i}(\omega) = 0 .$$

REMARK 1.1 (Rosenlicht differentials). There is a related explicit description of  $\omega_{X/S}$  for a family of nodal curves. Near a point where  $X/S \cong (xf = F) \subseteq \mathbb{C}^2 \times S$   $\omega_{C/S}$  is generated by  $dx/x$  and  $dy/y$  which satisfy

$$(1.24) \quad \frac{dx}{x} + \frac{dy}{y} = 0 .$$

DEFINITION 1.3. A nodal curve is *stable* if  $\omega_C$  is ample.

**Proposition 1.7.** *Let  $X \rightarrow S$  be a family of nodal curves. Then*

$$\{s \in S \mid X_s \text{ is stable}\}$$

*is Zariski open.*

PROOF. Let  $L$  be any line bundle on  $X$ . Then

$$\{s \in S \mid L|_{X_s} \text{ is ample}\}$$

is Zariski-open. This is Theorem 1.2.17 of [4].  $\square$

**THEOREM 1.8.** *A nodal curve  $C$  is stable if and only if  $\text{Aut}(C)$  is finite.*

PROOF. Say  $C$  has components  $C_1, \dots, C_s$  and nodes  $x_1, \dots, x_r$ . Write  $\{p_i, q_i\} = \nu^{-1}(x_i)$  for the preimage of the nodes under the normalization  $\nu$ . Write  $Q = \{p_1, q_1, \dots, p_r, q_r\}$ . Notice that  $\text{Aut}(C)$  is finite if and only if

$$\{\sigma \in \text{Aut}(C) \mid \sigma \text{ acts by 1 on } \{C_1, \dots, C_s\}\}$$

is finite.

Fix  $C_i$ . Note that  $\text{Aut}(C_i)$  is finite if and only if there are only finitely many automorphisms of  $\tilde{C}_i$  that fix  $Q \cap \tilde{C}_i$ . This is the case exactly when

- (1)  $g(\tilde{C}_i) \geq 2$ ;
- (2)  $g(\tilde{C}_i) = 1$ , and  $Q \cap \tilde{C}_i \neq \emptyset$ ; or
- (3)  $g(\tilde{C}_i) = 0$  and  $Q \cap \tilde{C}_i \geq 3$ .

By direct computation, these are precisely the cases where

$$2g(\tilde{C}_i) - 2 + \#(Q \cap \tilde{C}_i) > 0.$$

The left hand side is  $\deg(\omega_C|_{C_i})$ , by our description of the dualizing sheaf in terms of meromorphic differentials.

So we have shown that  $\text{Aut}(C)$  is finite if and only if the degree of the dualizing sheaf is positive on every component, which is equivalent to  $\omega_C$  being ample, i.e., to  $C$  being stable.  $\square$

**DEFINITION 1.4.** A *graph*  $G$  is a set  $X(G)$  together with an involution  $i : X(G) \rightarrow X(G)$  and a retraction  $r : X(G) \rightarrow X(G)^i$ . The vertices  $V(G)$ , half edges  $H(G)$ , and edges  $E(G)$  are defined as:

$$\begin{aligned} V(G) &= X(G)^i \\ H(G) &= X(G) \setminus V(G) \\ E(G) &= H(G)/i. \end{aligned}$$

We say  $r(h)$  is the vertex incident to  $h \in H(G)$ .

The *dual graph*  $G(C)$  of a nodal curve  $C$  is as follows. The vertices  $\{v_1, \dots, v_s\}$  correspond to the components  $C_1, \dots, C_s$ ; and the half-edges incident to  $v_i$  are given by the points of  $\tilde{C}_i \cap Q$ . An edge is made from a pair of half-edges corresponding to a pair  $\{p_i, q_i\}$ . The “genus function” assigns the genus of  $\tilde{C}_i$  to the corresponding vertex  $v_i$ . See Fig. 2 for examples.

We can read the stability off from the dual graph. Every vertex labelled with a 1 should have at least one incident edge, and all unlabelled vertices should have valence at least 3.

FIGURE 2. Two examples of genus 2 stable curves with their dual graphs below them. Notice we can read their stability off from the graphs. All unlabelled vertices have at least three incident edges, and the labelled one has one incident edge.

FIGURE 3. An example of an unstable genus 2 curve with its dual graph below it. Notice we can read the fact that it is unstable off of the graph. All three unlabelled vertices of valence less than 3.

Recall that the arithmetic genus of a curve  $C$  is

$$p_a(C) = 1 - \chi(\mathcal{O}_C) .$$

In particular, if  $C$  is connected then  $p_a(C) = h^1(\mathcal{O}_C)$ . Recall the Euler characteristic of a graph  $G$  is

$$\chi(G) = \#V(G) - \#E(G) .$$

Note if  $G$  is connected, then  $h^1(G) = 1 - \chi(G)$ . Also note that  $C$  is connected if and only if  $G(C)$  is connected. The dual graph also detects the arithmetic genus in the following sense.

**THEOREM 1.9.** *Let  $C$  be a nodal curve. Then*

$$(1.25) \quad p_a(C) = 1 - \chi(G(C)) + \sum_v g(v) .$$

**Corollary 1.10.** *If  $C$  is connected then*

$$(1.26) \quad p_a(C) = \sum_v g(v) + h^1(G) .$$

**PROOF OF THEOREM 1.9.** Proceed by induction on the number of nodes  $\#E(G) = \#C^{\text{sing}}$ . The base case is when  $E(G) = \emptyset$ , so the graph is just  $s$  vertices  $v_i$  with genus  $g(v_i)$ . Then

$$(1.27) \quad 1 - \chi(\mathcal{O}_C) = 1 - s + \sum_i g(v_i)$$

as desired.

Now suppose  $C'$  is obtained from  $C$  by gluing two smooth points  $p, q$  to  $x$ . Write  $\pi : C \rightarrow C'$ . Then we have an exact sequence of sheaves

$$(1.28) \quad 0 \rightarrow \mathcal{O}_{C'} \rightarrow \pi_* \mathcal{O}_C \rightarrow \mathcal{O}_X \rightarrow 0$$

which implies the Euler characteristic of the middle term is the Euler characteristic of the other two terms. Now since this gluing is proper and finite, it doesn't change the Euler characteristic. Altogether this gives us:

$$(1.29) \quad \chi(\mathcal{O}_C) = \chi(\pi_* \mathcal{O}_C) = \chi(\mathcal{O}_{C'}) + \chi(\mathcal{O}_X) = \chi(\mathcal{O}_{C'}) + 1 .$$

□

Lecture 5; January  
31, 2020

#### 4. Stable reduction

There are two statements. The first is the nodal reduction theorem (which does not involve stability) and the second is stabilization, which adds uniqueness. The reference is [1] chapter X, section 4. Write

$$(1.30) \quad \Delta = \{z \in \mathbb{C} \mid |z| < \epsilon\}$$

for a small disk. Write  $\Delta^\times = \Delta \setminus \{0\}$  for the punctured disk, both viewed as having one complex dimension.

Consider a flat proper surjective map  $\pi : X \rightarrow \Delta$  such that  $\pi|_{\Delta^\times}$  is a family of nodal curves. Write  $X^\bullet$  for the complement of the fiber over 0. Let  $k > 0$  be an integer. Consider the map  $\varphi_k : \Delta' \rightarrow \Delta$  from the disk to itself given by  $z \mapsto z^k$ . Note that  $\varphi_k$  is *not* a smooth map. Now we can construct a base change

$$(1.31) \quad \begin{array}{ccc} X_k^\bullet := X^\bullet \times_{\varphi_k} \Delta'^\times & \longrightarrow & X^\bullet \\ \downarrow \pi' & & \downarrow \pi \\ \Delta'^\times & \xrightarrow{\varphi_k} & \Delta^\times \end{array} .$$

**THEOREM 1.11** (Nodal reduction theorem). *Let  $\pi : X \rightarrow \Delta$  be a flat proper surjective map such that  $\pi|_{\Delta^\times}$  is a family of nodal curves. Then there exists an integer  $k > 0$  such that after a base change as above, the map  $\pi'$  extends to a family of nodal curves over  $\Delta$ .*

**THEOREM 1.12** (Stable reduction). *If  $\pi|_{\Delta^\times}$  is stable, then this extension can be chosen to be stable, and the fiber over 0 depends only on  $\pi|_{\Delta^\times}$  up to isomorphism.*

**REMARK 1.2.** This is related to separatedness of moduli spaces.

**REMARK 1.3.** The intuition is as follows. Let  $\Sigma$  be a class of objects with a moduli space  $\mathcal{M}$ , so that there is a universal family  $\mathcal{I} \rightarrow \mathcal{M}$  of objects in  $\Sigma$  such that any family of objects  $X \rightarrow S$  in  $\Sigma$ , is the pullback of the universal family under a unique morphism  $S \rightarrow \mathcal{M}$ . I.e.

$$(1.32) \quad \text{Hom}(-, \mathcal{M}) \cong \{\text{families of } \Sigma \text{ objects over } -\} .$$

If  $\mathcal{M}$  is separated, i.e., Hausdorff, then for  $\Delta^\times \rightarrow \mathcal{M}$  there exists at most one extension  $\Delta \rightarrow \mathcal{M}$ . If  $\mathcal{M}$  is compact and proper, then for  $\Delta^\times \rightarrow \mathcal{M}$  there exists a unique extension  $\Delta \rightarrow \mathcal{M}$ . The idea is to find open separated moduli subspace via stability condition.

Note that if we don't impose stability, given a family of nodal curves  $X^\bullet \rightarrow \Delta^\times$ , then it may extend in many different ways to a nodal family  $X' \rightarrow \Delta$ .

FIGURE 4. The constant family  $\pi : C \times \Delta \rightarrow \Delta$  as well as the blowup  $\text{Bl}_{(x,0)} C \times \Delta \rightarrow \Delta$ .

FIGURE 5. The surface given by  $xy = t^2 - t$ . Projection to the  $t$ -line has fibers which generically look like hyperbolas, but when the plane is tangent to the surface we get the union of two lines.

EXAMPLE 1.1. Consider a smooth curve  $C = (f = 0) \subseteq \mathbb{P}^2$ . Then  $C \times \Delta^\times \rightarrow \Delta^\times$  is a constant family which extends to  $C \times \Delta \rightarrow \Delta$ . Now for any  $x \in C$ ,  $C \times \Delta^\times$  also extends to  $\text{Bl}_{(x,0)} C \times \Delta$ . We can picture this as in Fig. 4.

The upshot is that moduli of nodal curves are not separated/Hausdorff.

Lecture 6; February  
3, 2020

### Interlude: Some motivating examples.

*Degeneration of a smooth curve to a nodal curve.* We should think of the total space as being a surface. Consider the surface in Fig. 5. This has two different rulings, as pictured in Fig. 5. As in Fig. 5, we can project this surface to a line by taking the intersection with parallel planes at different points of the line. Generically this gives us hyperbolas, but for two special values we get the union of two lines from the two different rulings. In particular this is given by the equation  $xy = t^2 - t$ . The node is exactly the point of tangency. So when we have a non-reduced curve, this is singular at every point on the curve.

*Degeneration of a smooth curve to a non-reduced curve.* Consider the surface defined by the equation  $x^3 + t(x + y + 1) = 0$ . At  $t = 0$  we just get a line with multiplicity 3. This looks something like Fig. 6.

*Understanding the base change and its fibers.* Again we consider a flat proper surjective map  $\pi : X \rightarrow \Delta$  such that  $\pi|_{\Delta^\times}$  is a family of nodal curves. For simplicity assume that in fact  $X = \mathbb{P}^1 \times \Delta$ . Consider the map  $\varphi_k : \Delta' \rightarrow \Delta$  from the disk to itself given by  $z \mapsto z^k$ .

FIGURE 6. The surface  $x^3 + t(x + y + 1) = 0$ . Projecting to the  $t$ -line gives us smooth fibers which degenerate to a line with multiplicity 3 at  $t = 0$ .

Note that  $\varphi_k$  is *not* a smooth map. In particular:

$$(1.33) \quad \varphi_k^{-1}(0) = \operatorname{Spec}(\mathbb{C}[\epsilon]/\epsilon^k) \ .$$

Consider a base change for a family of curves

$$(1.34) \quad \begin{array}{ccc} (\mathbb{P}^1 \times \Delta) \times_{\varphi_k} \Delta' & & \mathbb{P}^1 \times \Delta \\ \downarrow \pi' & & \downarrow \pi \\ \Delta' & \xrightarrow{\varphi_k} & \Delta \end{array} \ .$$

If we think of the preimage under  $\varphi_k \circ \pi'$  we have actually made things worse, since the preimage of 0 is:

$$(1.35) \quad (\varphi_k \circ \pi)^{-1}(0) \simeq \mathbb{P}^1 \times \operatorname{Spec}(\mathbb{C}[\epsilon]/\epsilon^k) \ .$$

But in our construction we are replacing  $\pi$  by  $\pi'$ , not  $\varphi_k \circ \pi'$ . The moral is that (at least for specific  $k$ ) this replacement makes things better.

### Proof of the nodal reduction theorem.

PROOF OF THEOREM 1.11. We will operate under the simplifying assumption that  $X^\bullet \rightarrow \Delta^\times$  is smooth. The first step is to resolve the singularities of  $X$ . This is easy since  $\dim X = 2$ . First we normalize to get something regular in codimension 1. Then we blowup the finitely many singular points, and normalize again if needed. This will give us  $X' \xrightarrow{\pi'} \Delta$  where  $X'$  is smooth, but the central fiber  $(\pi')^{-1}(0) = X'_0$  might have arbitrary singularities. To deal with this, we resolve the non-nodal singularities of  $X'_0$  so it is nodal.

Then locally  $X'$  is isomorphic to  $z = x^a y^b$  (i.e. a node) or  $z = x^c$  (i.e. a point of  $X_0^{\text{red}}$ ). Then we cover by finitely many such local charts and take

$$(1.36) \quad k = \operatorname{lcm}\{ab, c\} \ .$$

The idea is to enable us to unwind the maximal multiplicity crossing. Then

$$(1.37) \quad X'' = \varphi_k^* X'$$

is not necessarily normal, but we claim:

CLAIM 1.1.  $(X'')^\nu \xrightarrow{\pi'} \Delta'$  is a nodal family, where  $(X'')^\nu$  is the normalization.

First consider  $\pi'$  near a point where  $X' \cong (z = x^c)$ . Write  $z = \zeta^k$  and  $k = ch$  so that

$$(1.38) \quad x^c - z = x^c - \zeta^{ch} = \prod_{\omega^c=1} (x - \omega \zeta^k) .$$

Note that when  $z \neq 0$  this gives a disjoint union. Now we normalize to get  $\coprod_{\omega^c=1} (x - \omega \zeta^k)$ , a nodal family with smooth fibers.

Now consider  $\pi'$  near a point where  $X' \cong (z = x^a y^b)$ . Write  $k = rsuv$  where  $a = ru$ ,  $b = su$ , and  $(r, s) = 1$ . Write  $\zeta$  for the coordinate on  $\Delta'$ . Then  $X''$  is locally given by

$$(1.39) \quad 0 = x^a y^b - \zeta^k .$$

This is obviously not normal since we can choose elements here which satisfy a monic polynomial. In particular we can choose  $\omega$  a primitive  $u$ th root of unity, so we can factor this as:

$$(1.40) \quad (x^a y^b - \zeta^k) = \prod_{i=1}^u (x^r y^s - \omega^i \zeta^{rsu}) .$$

Now  $\omega \zeta^{vrs} = x^r y^s$  is a local equation on one branch, but is still not normal. Then we claim the following.

CLAIM 1.2. The normalization is given by a surface in three-space with local coordinates  $\zeta, \alpha, \beta$  with normalization map given by  $x = \alpha^s, y = \beta^r$ . The surface is locally given by  $\zeta^v = \alpha\beta$ .

To check that this is the normalization we need to check that

- (1) it is normal,
- (2) generically one-to-one, and
- (3) surjective.

To see it is normal, notice that  $\zeta^v = \alpha\beta$  is a toric surface. It is a standard fact that toric surfaces are normal. We now show it is generically one-to-one. Given  $(\alpha, \beta, \zeta)$  and  $(\alpha', \beta', \zeta')$  so that

$$(1.41) \quad \alpha^s = (\alpha')^s \quad \beta^r = (\beta')^r \quad \zeta = \zeta' .$$

This means  $\alpha' = \sigma\alpha$  for  $\sigma$  an  $s$ th root of unity, and similarly  $\beta' = \tau\beta$  for  $\tau$  an  $r$ th root of unity. But if  $\alpha$  and  $\beta$  are nonzero, then  $\alpha\beta = \alpha'\beta'$  implies  $\sigma\tau = 1$ , so  $\sigma = \tau = 1$ , so

$$(1.42) \quad (\alpha, \beta, \zeta) = (\alpha', \beta', \zeta') .$$

Since the points where  $\alpha$  and  $\beta$  are nonzero form an open dense set we are done.

Now consider  $(x, y, \zeta)$  such that  $x^r y^s = \zeta^{vrs}$ . Then we must find points  $(\alpha, \beta, \zeta)$  such that  $\alpha\beta = \zeta^v$  and  $x = \alpha^s$ , and  $y = \beta^r$ . Choose  $\alpha_0, \beta_0$  such that  $\alpha_0^s = x$  and  $\beta_0^r = y$ . The point being that  $\alpha_0 \cdot \beta_0 = \xi \zeta^v$  where  $\xi^{rs} = 1$ . Now write

$$(1.43) \quad 1 = mr + ns$$

so the coordinates are

$$(1.44) \quad \alpha = \alpha_0 \xi^{-mr} \quad \beta = \beta_0 \xi^{-ns} .$$

□

Now we claim that  $X'$  can be chosen stably if  $X|_{\Delta^\times}$  is stable.

Lecture 7; February 5, 2020

**THEOREM 1.13** (Stabilization theorem). *Let  $X \xrightarrow{\pi} \Delta$  be a family of nodal curves such that  $\pi|_{\Delta^\times}$  is stable. Then there is*

$$(1.45) \quad \begin{array}{ccc} X & \xrightarrow{\psi} & X' \\ & \searrow & \swarrow \\ & \Delta & \end{array}$$

such that

- (1)  $\psi : X|_{\Delta^\times} \rightarrow X'|_{\Delta^\times}$  is an isomorphism;
- (2) for each component  $C_i$  of the central fiber  $C = X_0$ ,  $\psi$  maps  $C_i$  either to a point, or birationally onto its image; and
- (3)  $X'$  is a family of stable curves.<sup>1,3</sup>

Moreover,  $X' \rightarrow \Delta$  is unique.

**REMARK 1.4.** The moral of the story is that

$$(1.46) \quad X' = \text{Proj}_\Delta \left( \bigoplus_{n \geq 0} \pi_* \left( \omega_{X/\Delta}^{\otimes n} \right) \right) .$$

Recall that when we take this big direct sum we get a sheaf of graded  $\mathcal{O}_\Delta$ -algebras, so it makes sense to take relative  $\text{Proj}_\Delta$  of this. The minimal model program deals with finite generation of things like this.

**PROOF.** The idea is to consider  $C = X_0$  with components  $C_0, \dots, C_s$ . Then we will look at

$$(1.47) \quad \{C_i \mid \omega_C|_{C_i} \text{ is not ample}\} = \{C_i \mid \deg(\omega_C|_{C_i}) \leq 0\} .$$

Call this set the set of unstable components. We continue with our simplifying assumption that  $X|_{\Delta^\times}$  is smooth and with connected fibers. Note that this implies this has arithmetic genus  $p_a(C) \geq 2$ . Then the set of unstable components is:

$$(1.48) \quad \{C_i \mid \omega_C|_{C_i} \text{ is not ample}\} = \{C_i \mid c_i \cong \mathbb{P}^1, \# \{C_i \cap \text{Cl}((C \setminus C_i))\} \leq 2\} .$$

Then we have the following observation from [1]. The union of the unstable components is a union of rational curves that intersect the rest of the curves (the stable components) at one or two points on the ends of the chain. Let  $C'$  be the curve obtained by contracting all unstable chains. Note that  $p_a(C') = p_a(C)$ .

**WARNING 1.1.** Now we reach an error in [1] (page 112, second sentence). In particular, they claim that by construction  $X'$  is stable. But this is false, as the following example shows.

**COUNTEREXAMPLE 1.** Let the following graph be the dual graph of  $C$ :

<sup>1,3</sup>So  $X' \rightarrow \Delta$  is flat and proper with nodal stable fibers.

with three unstable components (in red). Then after contracting the unstable chain, we get that  $C'$  has dual graph

$$2 \bullet \text{ --- } \bullet$$

which is not stable.

We will proceed by stabilizing the special fiber  $C$ , i.e. we consider  $\varphi : C \rightarrow C'$  such that

- (i)  $\varphi|_{C_i}$  is either constant or birational onto its image (and an isomorphism on  $C_i \cap C^{\text{smooth}}$ ).
- (ii)  $p_a(C') = p_a(C)$ , and
- (iii)  $C'$  is stable.

Now we construct

$$(1.49) \quad \begin{array}{ccc} X & \xrightarrow{\varphi'} & X' \\ & \searrow \varphi \quad \swarrow \pi' & \\ & \Delta & \end{array}$$

such that

- (i)  $X'$  is a stable family,
- (ii)  $\varphi'$  is an isomorphism on  $\Delta^\times$ ,
- (iii)  $X'_0 \cong C'$ , and
- (iv)  $\varphi'|_{X_0} = \varphi$ .

Given  $\psi : C \rightarrow C'$  as above with  $C'$  stable, let  $L_0$  be  $\varphi^* \omega_{C'}$ . Let  $d_i = \deg(L_0|_{C_i})$  and  $\underline{d} = \deg(L_0)$ . Note all  $d_i \geq 0$ . Now choose  $d_i$  sections of  $\pi$  that meet  $C_i$  at distinct smooth points of  $C$ . We can do this by Hensel's lemma. Write  $D_{i_1}, \dots, D_{i_{d_i}}$  for the images of these  $d_i$  sections. Write

$$(1.50) \quad D = \sum_{D_{i_j}} .$$

Then  $L = \mathcal{O}(D)$  is a line bundle on  $X$ , and

$$(1.51) \quad \underline{\deg}(L|_{X_0}) = \underline{\deg}(L_0) .$$

Then we make the following observations:

- $L$  is relatively ample on  $\Delta^\times$  (with degree  $2g - 2$ ),
- $L|_{X_0}$  is the pullback of an ample line bundle  $L'$  on  $C'$ .

**Lemma 1.14.** *For any line bundle  $M'$  on  $C'$ ,*

$$(1.52) \quad H^i(C', M') = H^i(C, \varphi^* M')$$

(for  $i \in \{0, 1\}$ ).

PROOF. The pullback induces an isomorphism on  $H^0$ , and

$$\begin{aligned} \chi(M') &= \chi(\mathcal{O}_{C'}) + \deg(M') \\ &= \chi(\mathcal{O}_C) + \deg(\varphi^* M') \\ &= \chi(\varphi^* M') . \end{aligned}$$

□

The consequences are as follows. For large  $n$ ,  $H^1(X_0, L^{\otimes n}) = 0$  (vanishing on  $C'$  by ampleness and Lemma 1.14). This implies  $h^0(X_s, L^{\otimes n})$  is a constant function of  $s \in \Delta$ . Therefore  $\pi_* L^{\otimes n}$  is locally free by Grauert's theorem.<sup>1.4</sup>

Now we choose  $n$  sufficiently large such that  $L^{\otimes n}$  is very ample on fibers over  $\Delta^\times$ , and pullbacks of very ample on  $C'$  to  $C$  (over 0). Then  $\pi_* L^{\otimes n}$  induces  $\psi : X \rightarrow \Delta \times \mathbb{P}^N$ . Then we have

$$(1.53) \quad \psi(X_0) \cong C'.$$

Take  $X' = \text{im}(\psi)$ . Note that  $X' \rightarrow \Delta$  is flat by the Hilbert polynomial criterion. This is the end of the proof of stable reduction.  $\blacksquare$

REMARK 1.5. When one is learning algebraic geometry, it is important to keep track of when global facts can be shown by showing things on fibers. E.g. Grauert's theorem, Hensel's lemma, and somehow Nakayama's lemma is at the heart of things.

DEFINITION 1.5. An  $n$ -pointed nodal curve is a pair  $(X; p_1, \dots, p_n)$  such that  $X$  is a nodal curve, and  $p_1, \dots, p_n$  are distinct smooth points of  $X$ .

DEFINITION 1.6. We say  $(X; p_1, \dots, p_n)$  is *stable* if and only if  $\omega_X(p_1 + \dots + p_n)$  is ample.

THEOREM 1.15.  $(X; p_1, \dots, p_n)$  is stable if and only if

$$(1.54) \quad \text{Aut}(X; p_1, \dots, p_n) = \{\sigma \in \text{Aut}(X) \mid \sigma(p_i) = p_i\}$$

is finite.

DEFINITION 1.7. A *family of pointed nodal curves* is a family of nodal curves  $\pi : X \rightarrow S$  with sections  $\sigma_1, \dots, \sigma_n$ :

$$(1.55) \quad \begin{array}{c} X \\ \pi \downarrow \left( \begin{array}{c} \nearrow \sigma_1 \\ \vdots \\ \searrow \sigma_n \end{array} \right) \\ S \end{array}$$

such that  $\{\sigma_i(S)\}$  are disjoint and contained in  $\pi^{\text{smooth}}$ .

Then there are generalizations of nodal reduction, stabilization, and stable reduction for pointed curves as well.

The idea is as follows. When we contract during the stabilization process, the marked points follow the contraction. See Fig. 7.

Then there is a theorem that forgetting marked points and stabilization actually behave well in families. So if we have a functor from  $S$  to the moduli space of stable curves (of a given genus) with  $n$ -marked points, we can get the moduli space of stable curves (of the same genus) with  $(n-1)$ -marked points in such a way that we actually have a natural transformation between the corresponding functors.

Lecture 9; February  
10, 2020

<sup>1.4</sup>Recall this says that if the dimension of  $H^i$  is constant, the sheaf is coherent, and the morphism is proper, the  $R^i\pi_*$  is locally free. See [3].

FIGURE 7. The left curve is unstable. When we stabilize, we contract to get a stable curve as on the right. Note that the marked points follow the contraction.

## CHAPTER 2

### Deformation theory

DEFINITION 2.1. A *deformation* of a proper (connected) scheme (a  $\mathbb{C}$ -analytic space)  $X$  is a flat and proper morphism  $\mathcal{X} \xrightarrow{\varphi} S$  to a pointed scheme  $(S, s)$  together with an isomorphism  $\mathcal{X}_s \xrightarrow{\sim} X$ .

An *infinitesimal deformation* is a deformation over  $S = \text{Spec } \mathbb{C}[\epsilon]/\epsilon^2$ .

A morphism of deformations is a cartesian square

$$(2.1) \quad \begin{array}{ccc} \mathcal{X} & \longrightarrow & \mathcal{X}' \\ \downarrow & & \downarrow \\ (S, s) & \longrightarrow & (S', s') \end{array}$$

such that the induced map

$$(2.2) \quad \begin{array}{c} X \xrightarrow{\sim} \mathcal{X}_s \rightarrow \mathcal{X}'_{s'} \xrightarrow{\sim} X \\ \quad \quad \quad \curvearrowright \end{array}$$

is the identity.

THEOREM 2.1. *If  $X$  is smooth then the isomorphism classes of infinitesimal deformations of  $X$  are in natural bijection with  $H^1(X, T_X)$ .*

PROOF. The first step is to find a natural map from the isomorphism classes of infinitesimal deformations to  $H^1(X, T_X)$ . Since  $X$  is smooth, we have a smooth map  $\mathcal{X} \rightarrow S = \text{Spec } \mathbb{C}[\epsilon]/\epsilon^2$  which gives rise to the short exact sequence

$$(2.3) \quad 0 \rightarrow T_X \rightarrow T_{\mathcal{X}} \rightarrow \varphi^* T_S \rightarrow 0$$

which gives us a long exact sequence on cohomology:

$$(2.4) \quad \begin{array}{ccccccc} 0 & \longrightarrow & H^0(X, T_X) & \longrightarrow & H^0(X, T_{\mathcal{X}}) & \longrightarrow & H^0(X, \varphi^* T_S) \xrightarrow{\delta} H^1(X, T_X) \longrightarrow \dots \\ & & & & & & \parallel \\ & & & & & & H^0(X, \mathcal{O}_X) \\ & & & & & & \parallel \\ & & & & & & \mathbb{C} \end{array}$$

so  $1 \in \mathbb{C}$  lands in some class  $\delta(1) \in H^1(X, T_X)$ .

Let  $\mathcal{X} \rightarrow S$  be an infinitesimal deformation,  $\mathcal{X}_0 \xrightarrow{\sim} X$ . Note that  $\mathcal{O}_X$  is locally free (of rank 2) as an  $\mathcal{O}_X$ -module. Now we cover  $\mathcal{X}$  by finitely many open  $U_\alpha$  such that  $\mathcal{O}_X|_{U_\alpha}$  is free. Let  $z_{\alpha_1}, \dots, z_{\alpha_n}$  be local coordinates on these  $U_{\alpha_i} \subseteq X$ , and let  $f_{\alpha\beta}$  be the transition functions, i.e.  $z_\alpha = f_{\alpha\beta} z_\beta$ . These functions satisfy

$$(2.5) \quad f_{\alpha\beta}(f_{\beta\gamma}(z_\gamma)) = f_{\alpha\gamma}(z_\gamma) \ .$$

Now consider  $\mathcal{X}$  as being glued from the  $U_\alpha \times S$ . In particular  $U_\alpha \times S$  is glued to  $U_\beta \times S$  along  $(U_\alpha \cap U_\beta) \times S$ . So we have  $z_\alpha$  and  $\epsilon z_\alpha$ , and

$$(2.6) \quad z_\alpha = \underbrace{f_{\alpha\beta}(z_\beta) + \epsilon g_{\alpha\beta}(z_\beta)}_{\tilde{f}_{\alpha\beta}(z_\beta)},$$

i.e. we write  $\tilde{f}_{\alpha\beta}$  for the new transition functions, and moreover, the new transition functions agree with the old ones up to  $\epsilon$ . This is the gluing data describing the construction of  $\mathcal{X}$  from the charts  $U_\alpha \times S$ .

REMARK 2.1. The geometric picture is that we start with some  $X$ , then we spread this out into a higher-dimensional fibration. So assuming we've shrunk  $U_\alpha$  sufficiently, it has no interesting topology, and if we look at it inside of the fibers all at once, this is just a cylinder  $U_\alpha \times S$ . So then the total space is glued out of these cylinders.

Then these have to satisfy the gluing condition

$$(2.7) \quad \tilde{f}_\alpha(\tilde{f}_{\beta\gamma}(z_\gamma)) = \tilde{f}_{\alpha\gamma}(z_\gamma)$$

$$(2.8) \quad = \underbrace{f_{\alpha\beta}(f_{\beta\gamma})}_{f_{\alpha\gamma}} + f_{\alpha\beta}(\epsilon g_{\beta\gamma}) + \epsilon g_{\alpha\beta}(f_{\beta\gamma}).$$

The first term just comes from gluing on  $X$ , and the second term can be thought of as a version of Leibniz' rule:

$$(2.9) \quad \frac{\partial f_{\alpha\beta}}{\partial z_\beta} g_{\beta\gamma} + g_{\alpha\beta} = g_{\alpha\gamma}.$$

Another way of writing this is that:

$$(2.10) \quad \Theta_{\alpha\beta} = (g_{\alpha_i\beta_i}) \begin{pmatrix} \partial/\partial z_{\alpha_1} \\ \vdots \\ \partial/\partial z_{\alpha_n} \end{pmatrix} \in H^0(U_{\alpha\beta}, T_X|_{U_{\alpha\beta}})$$

is a cocycle, so it defines a class:

$$(2.11) \quad [\Theta_{\alpha\beta}] \in H^1(X, T_X)$$

which is the image of 1 in  $H^1(X, T_X)$ .

So by direct calculation, every 1-cocycle on  $T_X$  comes from a deformation. The derived functor approach tells us that the map

$$(2.12) \quad \{\text{isomorphism classes of deformations}\} \rightarrow H^1(X, T_X)$$

is well-defined, and the cocycle approach tells us that it is surjective. Then cohomologous cocycles give rise to isomorphic deformations.  $\square$

The reference for this is [1, Chapter XI, section 2].
